Regression

- 1 Get Rstudio from
<https://rstudio.com/products/rstudio/download/>
- 2 If you have it already, make sure to upgrade to the latest
version (4.5.0).

It may take a while, **better do it at home!**

Typing version in the console you should get `minor = 5.0` (see next page):

Installation

Typing version in the console you should get minor = 5.0 :

```
> version

platform      x86_64-w64-mingw32
arch           x86_64
os             mingw32
...
major          4
minor          5.0
...
```

If this is not the case, try this:

```
install.packages("installr")

library(installr)

updateR()
```

Does it work now?

Linear Regression

How would you
transform the
following data?

Polynomial
Regression

- Basic definitions
 - Many windows:
 - The **console** (and output)
 - The **script**: a set of instructions
 - The **data** in memory
 - Others: viewer, help, etc
 - Working with R is basically about writing scripts.
 - Scripts are typically structured as follows:
 - Preamble: clean memory, call packages, define working directory
 - Call external datasource
 - Statistical analysis (graphs, regressions, etc.)

Polynomial
Regression

- Commands vs **comments** in the script.
You can write comments after the **#-symbol**

```
install.packages("installr") # here we are installing  
                             a package  
library(installr) # here we are asking R to call that  
                  package  
updateR() # here we are executing a command (it  
           wouldn't work without calling the package in the  
           first place)
```

- Select and execute line by line (or all in once) with
CTRL+Enter

Linear Regression

How would you
transform the
following data?

Polynomial
Regression

Before we start:

Download the files “tech_adoption.xlsx” and “yield_curve.xlsx” save them in a specific working directory (you may create a folder for this lecture)

Now open a script in R. (File → New file → R Script)

Save it in your working directory. (e.g. IEEA Code 1.R)
(remember to save your work regularly!)

Some basics

We usually start R-scripts with a preamble that cleans the workspace, determines the working directory, and calls packages.

```
#-----  
# Preamble  
#-----  
rm(list=ls()) # This command deletes everything from your  
              workspace.  
  
setwd("G:/My Drive/UniHalle/Courses/Empirical Econ  
      Analysis/") # Working directory (of YOUR computer!)  
  
#install.packages("openxlsx") # installing the package  
                              # for reading excel files (uncomment the first time)  
library(openxlsx) # we are telling R to use it  
  
#install.packages("stargazer") # installing the package (  
                              # uncomment the first time)  
library(stargazer) # For regression tables
```

Basic Plotting

Log Transformation

Linear Regression

How would you
transform the
following data?

Polynomial
Regression

Load the required packages and view the tech adoption data:

```
# Load packages
library(openxlsx)

# Read Excel file
tech <- read.xlsx("tech_adoption.xlsx")

# View first few rows
head(tech)
```

The console will show:

```
> # View first few rows
> head(tech)
  Year Users
1 2005     6
2 2006    55
3 2007   253
4 2008   128
5 2009   163
6 2010   359
```

Basic Plotting

Create a simple scatter plot of tech users over time:

```
# Basic scatter plot
plot(tech$Year, tech$Users,
     main = "Tech Adoption Over Time",
     xlab = "Year", ylab = "Users")
```

Log Transformation

Plotting log-transformed data:

```
# Plot log-transformed users
plot(tech$Year, log(tech$Users),
     main = "Log-Transformed Tech Adoption",
     xlab = "Year", ylab = "log(Users)")
```

Linear Regression

Run simple linear and log-linear regressions:

```
# Run linear regression
model_linear <- lm(Users ~ Year, data = tech)

# Show results
summary(model_linear)

# Run log-linear model
model_log <- lm(log(Users) ~ Year, data = tech)

# Show results
summary(model_log)
```

Display and compare results:

```
stargazer(model_linear, model_log,
           type = "text",
           title = "Tech Adoption: Linear vs Log-Linear Models",
           column.labels = c("Linear", "Log-Linear"),
           dep.var.labels = c("Users", "log(Users)"))
```

Linear Regression

Console output:

Tech Adoption: Linear vs Log-Linear Models

=====		
Dependent variable:		
	Users	log(Users)
	Linear	Log-Linear
	(1)	(2)

Year	200.094*** (25.205)	0.241*** (0.022)
Constant	-401,968.400*** (50,787.630)	-479.229*** (44.104)

Observations	21	21
R2	0.768	0.864
=====		
Note:	*p<0.1; **p<0.05; ***p<0.01	

Notice difference in R^2 .

How would you transform the following data?

Raw Nonlinear Relationships

Tech Adoption: Exponential Growth

$$y \sim \exp(x)$$

Education Returns: Logarithmic

$$y \sim \log(x)$$

Metabolic Scaling: Power Law

$$y \sim x^k$$

Yield Curve: Cubic Polynomial

$$y \sim x + x^2 + x^3$$

How would you transform the following data?

Transformed Relationships

Log-Transformed Tech Adoption

$$\log(y) \sim x$$

Education Returns: Logarithmic

$$y \sim \log(x)$$

Log-Log Metabolic Scaling

$$\log(y) \sim \log(x)$$

Yield Curve: Cubic Polynomial

$$y \sim x + x^2 + x^3$$

Polynomial Regression

Working with polynomial relationships:

```
# Read yield curve data
yield <- read.xlsx("yield_curve.xlsx")

# Basic plot
plot(yield$Maturity, yield$Yield,
     main = "Yield_Curve_by_Maturity",
     xlab = "Maturity", ylab = "Yield")
```

Polynomial Regression

Polynomial regression:

```
# Cubic polynomial model
model_poly <- lm(Yield ~ Maturity + I(Maturity^2) + I(
  Maturity^3),
               data = yield)

# Show results
summary(model_poly)
```

Comparing linear and polynomial models:

```
# Linear model for yield
model_linear_yield <- lm(Yield ~ Maturity, data = yield)

stargazer(yield_lm_linear, yield_lm,
          type = "text",
          title = "Yield_Curve:_Linear_vs_Polynomial_
            Models",
          column.labels = c("Linear", "Cubic"),
          dep.var.labels = c("Yield", "Yield"))
```
