Convergence rules (from Greene's textbook)

Implications

Takeaways

What does asymptotic mean?

- Asymptotic = as $n \rightarrow \infty$ (i.e., when having infinitely many obs.)
- Serves as approximation for large sample scenario
- Key related concepts:
 - Consistency
 - Convergence in probability / in distribution
 - Asymptotic variance
 - Law of Large Numbers, Central Limit Theorem

What changes when $n \rightarrow \infty$?

Convergence rules (from Greene's textbook)

Implications

Takeaways

Consider following estimators:

1 $\hat{\theta}_1 = \theta + 0.001 \cdot n$

2 $\hat{\theta}_2 = \theta + 10,000/n$

3 $\hat{\theta}_3 = \theta + 0.001$

Which one is more efficient when $n = 10$?

Which one is biased?

Which one is consistent?

Convergence in Distribution and the CLT

What changes when $n \rightarrow \infty$?

Convergence rules (from Greene's textbook)

Implications

Takeaways

- Many useful estimators are biased.
- **Consistency** = related concept: As $n \rightarrow \infty$, each $\hat{\beta}_j$ converges to the true population value β_j .
- Formally, this convergence is stochastic and called **convergence in probability**.
- We can use two equivalent notations for this:

$$\hat{\beta}_j \xrightarrow{p} \beta_j \quad \Leftrightarrow \quad \text{plim } \hat{\beta}_j = \beta_j$$

- The formal definition of this: For each (even tiny) $\varepsilon > 0$

$$\Pr(|\hat{\beta}_j - \beta_j| > \varepsilon) \rightarrow 0 \text{ as } n \rightarrow \infty$$

Consistency: the idea

Stochastic

Asymptotic normality

Convergence in Distribution and the CLT

What changes when $n \rightarrow \infty$?

Convergence rules (from Greene's textbook)

Implications

Takeaways

■ Consistency requires that

- $\mathbb{E}(\hat{\beta}_j) \rightarrow \beta_j$ as $n \rightarrow \infty$
- $\text{var}(\hat{\beta}_j) \rightarrow 0$ as $n \rightarrow \infty$

■ Therefore

- A biased estimator ($\mathbb{E}(\hat{\beta}_j) \neq \beta_j$) can be consistent if it is **asymptotically unbiased**, i.e. $\mathbb{E}(\hat{\beta}_j) \rightarrow \beta_j$ as $n \rightarrow \infty$
many highly relevant estimators have this feature.
- An unbiased estimator can be inconsistent if $\text{var}(\hat{\beta}_j) \not\rightarrow 0$ as $n \rightarrow \infty$
some relevant estimators have this feature.

Consistency: the idea

Consistency

Convergence in Distribution and the CLT

What changes when $n \rightarrow \infty$?

Convergence rules (from Greene's textbook)

Implications

Takeaways

Convergence in Probability and the LLN

Convergence in Probability:

$$X_n \xrightarrow{p} c \text{ if } \lim_{n \rightarrow \infty} P(|X_n - c| > \epsilon) = 0 \quad \forall \epsilon > 0$$

Notation: $\text{plim}(X_n) = c$

Intuition: As n grows, X_n gets arbitrarily close to c with probability approaching 1.

Law of Large Numbers (LLN):

- If $X_1, \dots, X_n$ are i.i.d. with $\mathbb{E}[X_i] = \mu$, then:

$$\bar{X}_n = \frac{1}{n} \sum_{i=1}^n X_i \xrightarrow{p} \mu$$

- Sample moments converge to population moments

Asymptotic variance

How **fast** (as $n \uparrow$) does the OLS variance converge to zero?

Recall, when $k = 2$ (univariate regression):

$$\text{var}(\hat{\beta}|x) = \frac{\sigma^2}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{\sigma^2}{n \text{var}(x)}$$

Note that variance falls at rate n

Hence, by variance-rule $\text{var}(a + b \cdot Y) = b^2 \text{var}(Y)$:

$$\begin{aligned}\text{var}(\hat{\beta} - \beta|x) &= \frac{\sigma^2}{n \text{var}(x)} \\ \text{var}[\sqrt{n}(\hat{\beta} - \beta)|x] &= (\sqrt{n})^2 \frac{\sigma^2}{n \text{var}(x)} \\ &= \frac{\sigma^2}{\text{var}(x)} \quad \text{root-n consistency!}\end{aligned}$$

Asymptotic variance

Recall that variances of $\hat{\beta}$ get smaller with higher n :

Asymptotic variance

Now not $\hat{\beta}$ but $\sqrt{n}(\hat{\beta} - \beta)$:

ASYMPTOTIC NORMALITY

Convergence in Distribution and the CLT

Convergence in Distribution:

- $X_n \xrightarrow{d} X$ if CDF of X_n converges to CDF of X
- The *shape* of distribution stabilizes

Central Limit Theorem (CLT):

- If $X_1, \dots, X_n$ are i.i.d. with $\mathbb{E}[X_i] = \mu$, $\text{var}(X_i) = \sigma^2$, then:

$$\sqrt{n}(\bar{X}_n - \mu) \xrightarrow{d} N(0, \sigma^2)$$

- Equivalently: $\frac{\bar{X}_n - \mu}{\sigma/\sqrt{n}} \xrightarrow{d} N(0, 1)$
- Standardized sample mean becomes normal regardless of population distribution

WHAT CHANGES WHEN $n \rightarrow \infty$?

Convergence rules (from Greene's textbook)

Rules for studying convergence:

THEOREM D.12 Slutsky Theorem

For a continuous function $g(x_n)$ that is not a function of n ,

$$\text{plim } g(x_n) = g(\text{plim } x_n). \quad \textbf{(D-6)}$$

See Greene, App. D.

Convergence rules (from Greene's textbook)

THEOREM D.14 Rules for Probability Limits

If x_n and y_n are random variables with $\text{plim } x_n = c$ and $\text{plim } y_n = d$, then

$$\text{plim}(x_n + y_n) = c + d, \quad (\text{sum rule}) \quad (\text{D-7})$$

$$\text{plim } x_n y_n = cd, \quad (\text{product rule}) \quad (\text{D-8})$$

$$\text{plim } x_n / y_n = c/d \quad \text{if } d \neq 0. \quad (\text{ratio rule}) \quad (\text{D-9})$$

If $\mathbf{W}_n$ is a matrix whose elements are random variables and if $\text{plim } \mathbf{W}_n = \mathbf{\Omega}$, then

$$\text{plim } \mathbf{W}_n^{-1} = \mathbf{\Omega}^{-1}. \quad (\text{matrix inverse rule}) \quad (\text{D-10})$$

If $\mathbf{X}_n$ and $\mathbf{Y}_n$ are random matrices with $\text{plim } \mathbf{X}_n = \mathbf{A}$ and $\text{plim } \mathbf{Y}_n = \mathbf{B}$, then

$$\text{plim } \mathbf{X}_n \mathbf{Y}_n = \mathbf{AB}. \quad (\text{matrix product rule}) \quad (\text{D-11})$$

Exercises

THEOREM D.16 Rules for Limiting Distributions

1. If $x_n \xrightarrow{d} x$ and $\text{plim } y_n = c$, then

$$x_n y_n \xrightarrow{d} cx, \quad (\text{D-13})$$

which means that the limiting distribution of $x_n y_n$ is the distribution of cx . Also,

$$x_n + y_n \xrightarrow{d} x + c, \quad (\text{D-14})$$

$$x_n / y_n \xrightarrow{d} x/c, \quad \text{if } c \neq 0. \quad (\text{D-15})$$

2. If $x_n \xrightarrow{d} x$ and $g(x_n)$ is a continuous function, then

$$g(x_n) \xrightarrow{d} g(x). \quad (\text{D-16})$$

This result is analogous to the Slutsky theorem for probability limits. For an example, consider the t_n random variable discussed earlier. The exact distribution of t_n^2 is $F[1, n]$. But as $n \rightarrow \infty$, t_n converges to a standard normal variable. According to this result, the limiting distribution of t_n^2 will be that of the square of a standard normal, which is chi-squared with one

Implications

Let us first distinguish between **sample** and **population** quantities:

- **Sample covariance:** $\widehat{\text{cov}}(x, y) = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})$
- **Population covariance:** $\text{cov}(x, y) = E[(x - E[x])(y - E[y])]$
- By LLN: $\widehat{\text{cov}}(x, y) \xrightarrow{P} \text{cov}(x, y)$
- Similarly: $\widehat{\text{var}}(x) \xrightarrow{P} \text{cov}(x)$

Hence, by convergence rules, in the simple model $y_i = \beta_1 + \beta_2 x_i + u_i$

$$\hat{\beta}_2 = \frac{\widehat{\text{cov}}(x, y)}{\widehat{\text{var}}(x)} \underset{A2}{=} \beta_2 + \frac{\widehat{\text{cov}}(x, u)}{\widehat{\text{var}}(x)}$$

we can take probability limits:

$$\text{plim}(\hat{\beta}_2) = \beta_2 + \frac{\text{plim } \widehat{\text{cov}}(x, u)}{\text{plim } \widehat{\text{var}}(x)} = \beta_2 + \frac{\text{cov}(x, u)}{\text{var}(x)} \underset{\text{cov}(x, u)=0}{=} \beta_2$$

Key conditions: $\boxed{\text{cov}(x, u) = 0, \mathbb{E}(u) = 0}$ (not the stronger requirement $\mathbb{E}[u|X] = 0$)

TAKEAWAYS

- No longer need of X-conditioning in $E(u|X) = 0$
Sufficient: $\mathbb{E}(u) = 0$ and $\mathbb{E}(X'u) = 0$

- No longer need of normal errors assumption.
With $\mathbb{E}(\mathbf{x}'\mathbf{x}) = \mathbf{A}$,

$$\sqrt{n}(\hat{\beta} - \beta) \overset{a}{\sim} (\mathbf{0}, \sigma^2 \mathbf{A}^{-1})$$

- Normal distribution instead of t-stat.
- Yet all other issues remain (omitted variable biases, heteroskedasticity, simultaneity, etc.).
